City/Highway Driving

Inherent in the "Combined" or "55/45" MPG calculation is the apportionment of the miles into those for which the "city" MPG number is an appropriate measure and those for which the "highway" MPG number is also appropriate.

If the travel of a vehicle or a group of vehicles can be divided into, say, two modes of travel, then the MPG for that total travel can be calculated as:

$$\begin{array}{ccc} \texttt{MPG}_{\texttt{AVE}} & = & \underline{\texttt{Total Miles}} \\ & & \texttt{Total Gallons} \end{array}$$

If the two modes of travel are urban (represented by the city MPG) and non-urban (represented by the highway MPG), then

Noting that gallons =
$$\frac{\text{Miles}}{\text{MPG}}$$

and since city fraction is defined as urban miles/total miles, if we divide top and bottom by total miles (which equals urban miles plus non-urban miles), we get

Looking at just city fraction (CF), since highway fraction = 1-CF, and the value for city fraction, we obtain

City/Highway Driving

For the case where CF = 0.55, we get the "55/45" MPG definition, namely,

When the combined MPG value was first introduced in the early 1970s, the appropriate value was 55 percent for the city fraction and 45 percent for the highway fraction. Even though these values have been institutionalized, for example, in the fuel economy standards, they were changing. They were changing before the 1970s and continue to change. The values, obtained from the Department of Transportation's VM-1 tables, are listed in Table D-1. Over the years, the city fraction has increased, reflecting the larger growth in urban vehicle miles traveled (VMT). This would be expected to have a larger negative effect on combined MPG since a higher city fraction weights the city MPG more, and the city MPG is almost always lower than the highway MPG.

The city fractions and MPG values used for Figure C1 which shows the effect of CF on average MPG are given in the Tables below. The values are all derived from the DOT VM-1 tables published yearly by the U.S. Department of Transportation in their publication *Highway Statistics*.

For the calculations for cars, the car vector was used; for trucks, the truck vector was used; and for the "both" calculation, the "both" vector was used. Cars and light trucks may have had different city fractions in the past, but they are essentially the same now.

Figure C1 shows the trends in adjusted city/highway—weighted MPG versus time for cars, trucks, and cars and trucks combined. For each strata on this figure, one line shows the values as estimated with a constant 55/45 value for the city fraction/highway fraction; the other line shows the value using the actual values from Table C-1.

City/Highway Driving

If the adjusted MPG values provide an improved estimate of the MPG likely to be achieved in actual use, then accounting for the increase in city fraction should improve the estimate. In this way, the combined car and light truck Lab MPG number of 24.4 MPG can be adjusted to 20.8 using the 0.90 and 0.78 city and highway fuel economy adjustment factors, and if the change in city fraction is accounted for, a value of 20.4 MPG for the onroad MPG of the combined model year 2003 new vehicle fleet is obtained.

Fuel Economy by Model Year The Influence of City Driving

City/Highway Driving

Considering the trends in the fuel economy of cars, light trucks, and the combined fleet, it is usually the case that the combined 55/45 MPG value is considered. In addition to the city fraction, the relationship between the highway MPG and the city MPG influences the result of the calculation. The trend in the ratio of highway MPG to city MPG is shown on Figure C2. In the mid 1970s, the value was about 1.4. The overall influence since 1975 has tended toward improved 55/45 MPG, since the highway MPG values have gone up slightly or remained about the same.

Ratio: Highway to City Fuel Economy
